# Delphes, a framework for fast simulation of a generic collider experiment

S. Ovyn\*, X. Rouby, V. Lemaître

Center for Particle Physics and Phenomenology (CP3), Université catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium

#### **Abstract**

It is sometimes difficult to know whether theoretical predictions can be observed in a high energy collider experiment, especially when expected experimental signature involve jets and missing transverse energy. For this purpose, we have designed a new C++-based framework, *Delphes*, performing a fast multipurpose detector response simulation. The simulation includes a tracking system, embedded into a magnetic field, calorimeters and a muon system, and possible very forward detectors arranged along the beamline. The framework is interfaced to standard file formats (e.g. Les Houches Event File or HepMC) and outputs observables such as isolated leptons, missing transverse energy and collection of jets which can be used for dedicated analyses. The simulation of the detector response takes into account the effect of magnetic field, the granularity of the calorimeters and subdetector resolutions. A simplified preselection can also be applied on processed events for trigger emulation. Detection of very forward scattered particles relies on the transport in beamlines with the *Hector* software. Finally, the FROG 2D/3D event display is used for visualisation of the collision final states.

Preprint: CP3-09-01, arXiv:0903.2225 [hep-ph]

#### **PROGRAM SUMMARY**

Program Title: DELPHES
Current version: 1.8
Journal Reference:
Catalogue identifier:
Distribution format: tar.gz
Programming language: C++

External routines/libraries: ROOT environment

Subprograms used: HepMC, StdHEP, FASTJET, Hector, FROG. All provided within Delphes distribution.

URL: http://www.fynu.ucl.ac.be/delphes.html

Key words: Delphes, detector simulation, event reconstruction, trigger, LHC

PACS: 29.85.-c, 07.05.Tp, 29.90.+r, 29.50.+v

#### 1. Introduction

Multipurpose detectors at high energy colliders are very complex systems. Their simulation is in general performed by means of the GEANT [1] package and final observables used for analyses usually require sophisticated reconstruction algorithms.

Email address: severine.ovyn@uclouvain.be (S. Ovyn)

<sup>\*</sup>Corresponding author: +32.10.47.32.29.

This complexity is handled by large collaborations, and data and the expertise on reconstruction and simulation software are only available to their members. Precise data analyses require a full detector simulation, including transport of the primary and secondary particles through the detector material accounting for the various detector inefficiencies, the dead material, the imperfections and the geometrical details. Such simulation is very complicated, technical and requires a large CPU power. On the other hand, phenomenological studies, looking for the observability of given signals, may require only fast but realistic estimates of the expected signal signatures and their associated backgrounds.

A new framework, called *Delphes* [2], is introduced here, for the fast simulation of a general-purpose collider experiment. Using this framework, observables such as cross-sections and efficiencies after event selection can be estimated for specific reactions. Starting from the output of event generators, the simulation of the detector response takes into account the subdetector resolutions, by smearing the kinematics of final-state particles (i.e. those considered as stable by the event generator <sup>1</sup>).

*Delphes* includes the most crucial experimental features, such as (Fig. 1):

- 1. the geometry of both central and forward detectors,
- 2. the effect of magnetic field on tracks,
- 3. the reconstruction of photons, leptons, jets, b-jets,  $\tau$ -jets and missing transverse energy,
- 4. a lepton isolation,
- 5. a trigger emulation,
- 6. an event display.

Although *Delphes* yields much realistic results than a simple "parton-level" analysis, it has some limitations. Detector geometry is idealised, being uniform, symmetric around the beam axis, and having no cracks nor dead material. Secondary interactions, multiple scatterings, photon conversion and bremsstrahlung are also neglected.

Several common datafile formats can be used as input in *Delphes* [a], in order to process events from many different generators. *Delphes* creates output data in a ROOT ntuple [3]. This output contains a copy of the generator-level data, the analysis data objects after reconstruction, and possibly the results of the trigger emulation [b]. In option *Delphes* can produce a reduced output file in \*.lhco text format, which is limited to the list of the reconstructed high-level objects in the final states [c].

#### 2. Simulation of the detector response

The overall layout of the multipurpose detector simulated by *Delphes* is shown in Fig. 2. It consists in a central tracking system (TRACKER) surrounded by an electromagnetic and a hadron

Table 1: Default extension in pseudorapidity  $\eta$  of the different subdetectors. Full azimuthal  $(\phi)$  acceptance is assumed.

	$\eta$	$\phi$
TRACKER	[-2.5; 2.5]	$[-\pi;\pi]$
ECAL, HCAL	[-1.7; 1.7]	$[-\pi;\pi]$
ECAL, HCAL endcaps	[-3; -1.7] & [1.7; 3]	$[-\pi;\pi]$
FCAL	[-5; -3] & [3; 5]	$[-\pi;\pi]$
MUON	[-2.4; 2.4]	$[-\pi;\pi]$

calorimeters (ECAL and HCAL, each with a central region and two endcaps) and two forward calorimeters (FCAL). Finally, a muon system (MUON) encloses the central detector volume.

A detector card [e] allows a large spectrum of running conditions by modifying basic detector parameters, including calorimeter and tracking coverage and resolution, thresholds or jet algorithm parameters. Even if *Delphes* has been developed for the simulation of general-purpose detectors at the LHC (namely, CMS and ATLAS), this input parameter file interfaces a flexible parametrisation for other cases, e.g. at future linear colliders [f]. If no detector card is provided, predefined values based on "typical" CMS acceptances and resolutions are used. The geometrical coverage of the various subsystems used in the default configuration are summarised in Tab. 1. The detector is assumed to be strictly symmetric around the beam axis.

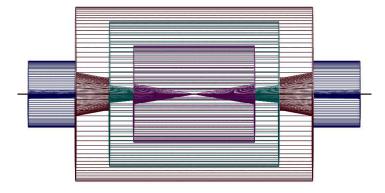

Figure 2: Profile of layout of the generic detector geometry assumed in *Delphes*. The innermost layer, close to the interaction point, is a central tracking system (pink). It is surrounded by a central calorimeter volume (green) with both electromagnetic and hadronic sections. The outer layer of the central system (red) is muon system. In addition, two end-cap calorimeters (blue) extend the pseudorapidity coverage of the central detector. Additional forward detectors are not depicted.

#### 2.1. Magnetic field

In addition to the subdetectors, the effects of a solenoidal magnetic field are simulated for the charged particles [h]. This affects the position at which charged particles enter the calorimeters and their corresponding tracks. The field extension is limited to the tracker volume and is in particular not applied for muon chambers. However, this is not a limiting factor as the resolution applied for muon reconstruction is the one expected by the experiment, which

<sup>&</sup>lt;sup>1</sup>In the current *Delphes* version, particles other than electrons ( $e^{\pm}$ ), photons ( $\gamma$ ), muons ( $\mu^{\pm}$ ), neutrinos ( $\nu_e$ ,  $\nu_{\mu}$  and  $\nu_{\tau}$ ) and neutralinos are simulated as hadrons for their interactions with the calorimeters. The simulation of stable particles beyond the Standard Model should therefore be handled with care [d].

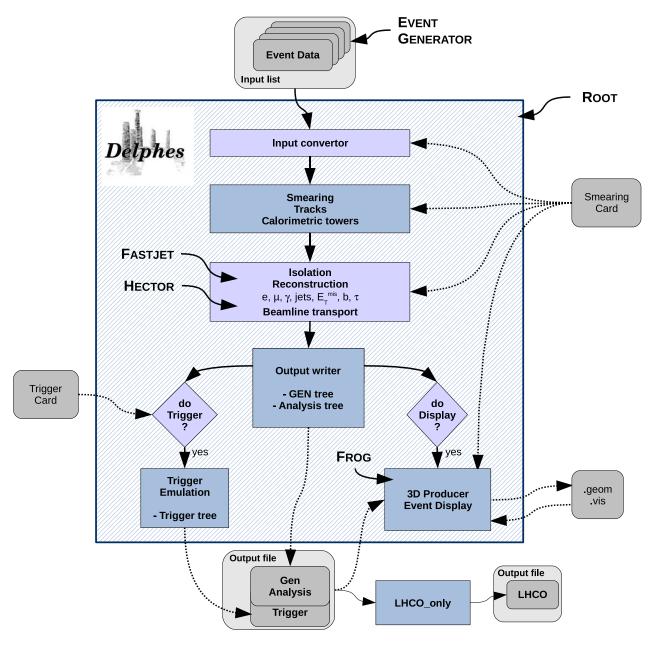

Figure 1: Flow chart describing the principles behind *Delphes*. Event files coming from external Monte Carlo generators are read by a converter stage (top). The kinematics variables of the final-state particles are then smeared according to the tunable subdetector resolutions. Tracks are reconstructed in a simulated solenoidal magnetic field and calorimetric cells sample the energy deposits. Based on these low-level objects, dedicated algorithms are applied for particle identification, isolation and reconstruction. The transport of very forward particles to the near-beam detectors is also simulated. Finally, an output file is written, including generator-level and analysis-object data. If requested, a fully parametrisable trigger can be emulated. Optionally, the geometry and visualisation files for the 3D event display can also be produced. All user parameters are set in the *Detector/Smearing Card* and the *Trigger Card*.

consequently includes the effects of the magnetic field within the muon system.

#### 2.2. Tracks reconstruction

Every stable charged particle with a transverse momentum above some threshold and lying inside the detector volume covered by the tracker provides a track. By default, a track is assumed to be reconstructed with 90% probability if its transverse momentum  $p_T$  is higher than 0.9 GeV/c and if its pseudorapidity  $|\eta| \le 2.5$  [i]. No smearing is currently applied on tracks.

#### 2.3. Calorimetric cells

The response of the calorimeters to energy deposits of incoming particles depends on their segmentation and resolution, as well as on the nature of the particles themselves. In CMS and ATLAS detectors, for instance, the calorimeter characteristics are not identical in every direction, with typically finer resolution and granularity in the central regions [5, 6]. It is thus very important to compute the exact coordinates of the entry point of the particles into the calorimeters, via the magnetic field calculations.

The smallest unit for geometrical sampling of the calorimeters is a *cell*; it segments the  $(\eta, \phi)$  plane for the energy measurement. No longitudinal segmentation is available in the simulated calorimeters. *Delphes* assumes that ECAL and HCAL have the same segmentations and that the detector is symmetric in  $\phi$  and with respect to the  $\eta=0$  plane [1]. Fig. 3 illustrates the default calorimeter segmentation.

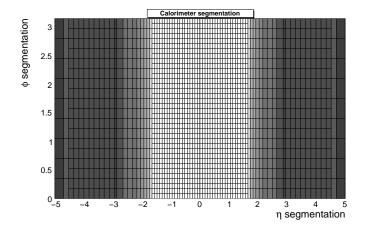

Figure 3: Default segmentation of the calorimeters in the  $(\eta, \phi)$  plane. Only the central detectors (ECAL, HCAL) and FCAL are considered.  $\phi$  angles are expressed in radians.

The calorimeter response is parametrised through a Gaussian smearing of the accumulated cell energy with a variance  $\sigma$ :

$$\frac{\sigma}{E} = \frac{S}{\sqrt{E}} \oplus \frac{N}{E} \oplus C,\tag{1}$$

where S, N and C are the *stochastic*, *noise* and *constant* terms, respectively, and  $\oplus$  stands for quadratic additions [j].

In the default parametrisation, ECAL and HCAL are assumed to cover the pseudorapidity range  $|\eta| < 3$ , and FCAL between 3.0 and 5.0, with different response to electromagnetic objects  $(e^{\pm}, \gamma)$  or hadrons. Muons and neutrinos are assumed not to interact with the calorimeters [d]. The default values of the stochastic, noise and constant terms are given in Tab. 2.

Table 2: Default values for the resolution of the central and forward calorimeters (for both electromagnetic and hadronic parts). Resolution is parametrised by the *stochastic* (S), *noise* (N) and *constant* (C) terms (Eq. 1) [g].

	S (GeV <sup>1/2</sup> )	N (GeV)	С
ECAL	0.05	0.25	0.0055
ECAL, end caps	0.05	0.25	0.0055
FCAL, e.m. part	2.084	0	0.107
HCAL	1.5	0	0.05
HCAL, end caps	1.5	0	0.05
FCAL, had. part	2.7	0	0.13

Electrons and photons leave their energy in the electromagnetic

parts of the calorimeters (ECAL and FCAL, e.m.), while charged and neutral final-state hadrons interact with the hadronic parts (HCAL and FCAL, had.). Some long-living particles, such as the  $K_s^0$  and  $\Lambda$ 's, with lifetime  $c\tau$  smaller than 10 mm are considered as stable particles by the generators although they may decay before the calorimeters. The energy smearing of such particles is therefore performed using the expected fraction of the energy, determined according to their decay products, that would be deposited into the ECAL ( $E_{\rm ECAL}$ ) and into the HCAL ( $E_{\rm HCAL}$ ). Defining F as the fraction of the energy leading to a HCAL deposit, the two energy values are given by

$$\begin{cases} E_{\text{HCAL}} = E \times F \\ E_{\text{ECAL}} = E \times (1 - F) \end{cases}$$
 (2)

where  $0 \le F \le 1$ . The electromagnetic part is handled similarly as for electrons and photons. The resulting calorimetry energy measurement given after the application of the smearing is then  $E = E_{\text{HCAL}} + E_{\text{ECAL}}$ . For  $K_S^0$  and  $\Lambda$  hadrons, the energy fraction is F is assumed to be 0.7 [k].

No sharing between neighbouring cells is implemented when particles enter a cell very close to its geometrical edge. Due to the finite segmentation, the smearing, as defined in Eq. 1, is applied directly on the accumulated electromagnetic and hadronic energies of each calorimetric cell. The calorimetric cells enter in the calculation of the missing transverse energy (MET), and are used as input for the jet reconstruction algorithms.

## 3. High-level object reconstruction

The output file created by Delphes [m] stores the final collections of particles  $(e^{\pm}, \mu^{\pm}, \gamma)$  and objects (light jets, b-jets,  $\tau$ -jets,  $E_T^{miss}$ ). In addition, some detector data are added, such as tracks, calorimetric cells and hits in the very forward detectors (ZDC, RP220 and FP420, see Sec. 5). While electrons, muons and photons are easily identified, other quantities are more difficult to evaluate as they rely on sophisticated algorithms (e.g. jets or missing energy).

For most of these objects, their four-momentum and related quantities are directly accessible in *Delphes* output  $(E, \vec{p}, p_T, \eta)$  and  $\phi$ ). Additional properties are available for specific objects (like the charge and the isolation status for  $e^{\pm}$  and  $\mu^{\pm}$ , the result of application of b-tag for jets and time-of-flight for some detector hits).

#### 3.1. Photon and charged lepton

From here onwards, *electrons* refer to both positrons  $(e^+)$  and electrons  $(e^-)$ , and *charged leptons* refer to electrons and muons  $(\mu^{\pm})$ , leaving out the  $\tau^{\pm}$  leptons as they decay before being detected.

The electron, muon and photon collections contains only the true final-state particles identified via the generator-data. In addition, these particles must pass fiducial cuts taking into account the magnetic field effects and some additional reconstruction cuts.

Consequently, no fake candidates enter these collections. However, when needed, fake candidates can be added into the collections at the analysis level, when processing *Delphes* output data. As effects like bremsstrahlung are not taken into account along the lepton propagation in the tracker, no clustering is needed for the electron reconstruction in *Delphes*.

## Electrons and photons

Real electron  $(e^{\pm})$  and photon candidates are associated to the final-state collections if they fall into the acceptance of the tracking system and have a transverse momentum above some threshold (default:  $p_T > 10~{\rm GeV/c}$ ). Assuming a good measurement of the track parameters in the real experiment, the electron energy can be reasonably recovered. *Delphes* assumes a perfect algorithm for clustering and Brehmstrahlung recovery. Electron energy is smeared according to the resolution of the calorimetric cell where it points to, but independently from any other deposited energy is this cell. Electrons and photons may create a candidate in the jet collection.

#### Muons

Generator-level muons entering the muon detector acceptance (default:  $-2.4 \le \eta \le 2.4$ ) and overpassing some threshold (default:  $p_T > 10~{\rm GeV}/c$ ) are considered as good candidates for analyses. The application of the detector resolution on the muon momentum depends on a Gaussian smearing of the  $p_T$  [n]. Neither  $\eta$  nor  $\phi$  variables are modified beyond the calorimeters: no additional magnetic field is applied. Multiple scattering is neglected. This implies that low energy muons have in Delphes a better resolution than in a real detector. At last, the particles which might leak out of the calorimeters into the muon systems (punch-through) are not considered as muon candidates in Delphes.

## Charged lepton isolation

To improve the quality of the contents of the charged lepton collections, isolation criteria can be applied. This requires that electron or muon candidates are isolated in the detector from any other particle, within a small cone. In *Delphes*, charged lepton isolation demands that there is no other charged particle with  $p_T > 2~{\rm GeV}/c$  within a cone of  $\Delta R = \sqrt{\Delta \eta^2 + \Delta \phi^2} < 0.5$  centered on the cell associated to the charged lepton  $\ell$ , obviously taking the magnetic field into account.

The result (i.e. *isolated* or *not*) is added to the charged lepton measured properties. In addition, the sum  $P_T$  of the transverse momenta of all tracks but the lepton one within the isolation cone is provided [o]:

$$P_T = \sum_{i \neq \ell}^{\text{tracks}} p_T(i)$$

No calorimetric isolation is applied, but the charged lepton collections contain also the ratio  $\rho_{\ell}$  between (1) the sum of the transverse energies in all calorimetric cells in a  $N \times N$  grid around the lepton, and (2) the lepton transverse momentum [p]:

$$\rho_{\ell} = \frac{\sum_{i} E_{T}(i)}{p_{T}(\ell)}, i \text{ in } N \times N \text{ grid centred on } \ell.$$

## 3.2. Jet reconstruction

A realistic analysis requires a correct treatment of partons which have hadronised. Therefore, the most widely currently used jet algorithms have been integrated into the *Delphes* framework using the FastJet tools<sup>2</sup>. Six different jet reconstruction schemes are

available [8, r]. For all of them, the calorimetric cells are used as inputs. Jet algorithms differ in their sensitivity to soft particles or collinear splittings, and in their computing speed performances.

## Cone algorithms

- 1. *CDF Jet Clusters* [9]: Cone algorithm forming jets by combining cells lying within a circle (default radius  $\Delta R = 0.7$ ) in the  $(\eta, \phi)$  space. Jets are seeded by all cells with transverse energy  $E_T$  above a given threshold (default:  $E_T > 1$  GeV) [t].
- 2. *CDF MidPoint* [10]: Cone algorithm with additional "midpoints" (energy barycentres) in the list of seeds.
- 3. Seedless Infrared Safe Cone [11]: The SISCone algorithm is simultaneously insensitive to additional soft particles and collinear splittings.

#### Recombination algorithms

The next three jet algorithms rely on recombination schemes where calorimeter cell pairs are successively merged:

- 4. Longitudinally invariant  $k_t$  jet [12],
- 5. Cambridge/Aachen jet [13],
- 6. Anti  $k_t$  jet [14], where hard jets are exactly circular in the  $(y, \phi)$  plane.

The recombination algorithms are safe with respect to soft radiations (*infrared*) and collinear splittings. Their implementations are similar except for the definition of the *distances* used during the merging procedure.

By default, reconstruction uses the CDF cone algorithm. Jets are stored if their transverse energy is higher than 20 GeV [s].

#### Energy flow

In jets, several particle can leave their energy into a given calorimetric cell, which broadens the jet energy resolution. However, the energy of charged particles associated to jets can be deduced from their reconstructed track, thus providing a way to identify some of the components of cells with multiple hits. When the *energy flow* is switched on in *Delphes*, the energy of tracks pointing to calorimetric cells is subtracted and smeared separately, before running the chosen jet reconstruction algorithm. This option allows a better jet *E* reconstruction [u].

# 3.3. b-tagging

A jet is tagged as b-jets if its direction lies in the acceptance of the tracker and if it is associated to a parent b-quark. By default, a b-tagging efficiency of 40% is assumed if the jet has a parent b quark. For c-jets and light jets (i.e. originating in u, d, s quarks or in gluons), a fake b-tagging efficiency of 10% and 1% respectively is assumed [v]. The (mis)tagging relies on the true parton identity of the most energetic parton within a cone around the  $(\eta, \phi)$  region, with a radius equal to the one used to reconstruct the jet (default:  $\Delta R$  of 0.7). In current version of Delphes, the displacement of secondary vertices is not simulated.

<sup>&</sup>lt;sup>2</sup>A more detailed description of the jet algorithms is given in the User Manual, in appendix.

#### 3.4. τ identification

Jets originating from  $\tau$ -decays are identified using a procedure consistent with the one applied in a full detector simulation [5]. The tagging relies on two properties of the  $\tau$  lepton. First, 77% of the  $\tau$  hadronic decays contain only one charged hadron associated to a few neutrals (Tab. 3). Secondly, the particles arisen from the  $\tau$  lepton produce narrow jets in the calorimeter (this is defined as the jet *collimation*).

Table 3: Branching ratios for  $\tau^-$  lepton [15].  $h^\pm$  and  $h^0$  refer to charged and neutral hadrons, respectively.  $n \ge 0$  and  $m \ge 0$  are integers.

T4!- 1	
Leptonic decays	
$ au^-  ightarrow e^-  ar{ u}_e   u_ au$	17.9%
$ au^-  ightarrow \mu^-  ar{ u}_\mu   u_ au$	17.4%
Hadronic decays	
$ au^-  ightarrow h^-  (n  imes h^\pm)  (m  imes h^0)  v_ au$	64.7%
$ au^-  ightarrow h^-  (m  imes h^0)  v_ au$	50.1%
$\tau^- \to h^-  h^+ h^- (m \times h^0)  \nu_\tau$	14.6%

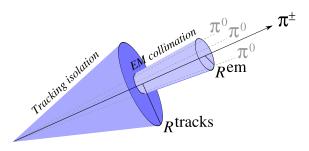

Figure 4: Illustration of the identification of  $\tau$ -jets (1-prong). The jet cone is narrow and contains only one track. The small cone serves to apply the *electromagnetic collimation*, while the broader cone is used to reconstruct the jet originating from the  $\tau$ -decay.

Table 4: Default values for parameters used in  $\tau$ -jet reconstruction algorithm. Electromagnetic collimation requirements involve the inner *small* cone radius  $R^{\rm em}$ , the minimum transverse energy for calorimetric cells  $E_T^{\rm cell}$  and the collimation factor  $C_\tau$ . Tracking isolation constrains the number of tracks with a significant transverse momentum  $p_T^{\rm tracks}$  in a cone of radius  $R^{\rm tracks}$ . Finally, the  $\tau$ -jet collection is purified by the application of a cut on the  $p_T$  of  $\tau$ -jet candidates [w].

Electromagne	<b>Electromagnetic collimation</b>				
$R^{\mathrm{em}}$	0.15				
$\min E_T^{\mathrm{cell}}$	1.0 GeV				
$C_{ au}$	0.95				
Tracking isolation					
$R^{\text{tracks}}$	0.4				
min $p_T^{\text{tracks}}$	2  GeV/c				
au-jet candidate					
$\min p_T$	10 GeV/ <i>c</i>				

#### Electromagnetic collimation

To use the narrowness of the  $\tau$ -jet, the *electromagnetic collimation*  $C_{\tau}$  is defined as the sum of the energy of cells in a small cone of radius  $R^{\rm em}$  around the jet axis, divided by the energy of the reconstructed jet. To be taken into account, a calorimeter cell should have a transverse energy  $E_T^{\rm cell}$  above a given threshold. A large fraction of the jet energy is expected in this small cone. This fraction, or *collimation factor*, is represented in Fig. 5 for the default values (see Tab. 4).

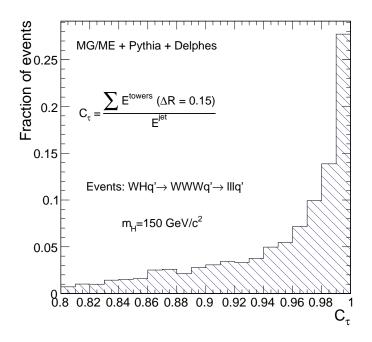

Figure 5: Distribution of the electromagnetic collimation  $C_{\tau}$  variable for true  $\tau$ -jets, normalised to unity. This distribution is shown for associated WH photoproduction [16], where the Higgs boson decays into a  $W^+W^-$  pair. Each W boson decays into a  $\ell\nu_{\ell}$  pair, where  $\ell=e,\mu,\tau$ . Events generated with MadGraph/MadEvent [17]. Final state hadronisation is performed by Pythia [18]. Histogram entries correspond to true  $\tau$ -jets, matched with generator-level data.

#### Tracking isolation

The tracking isolation for the  $\tau$  identification requires that the number of tracks associated to particles with significant transverse momenta is one and only one in a cone of radius  $R^{\text{tracks}}$  (3–prong  $\tau$ -jets are dropped). This cone should be entirely incorporated into the tracker to be taken into account. Default values of these parameters are given in Tab. 4.

#### Purity

Once both electromagnetic collimation and tracking isolation are applied, a threshold on the  $p_T$  of the  $\tau$ -jet candidate is requested to purify the collection. This procedure selects  $\tau$  leptons decaying hadronically with a typical efficiency of 66%.

#### 3.5. Missing transverse energy

In an ideal detector, momentum conservation imposes the transverse momentum of the observed final state  $\overrightarrow{p_T}^{\text{obs}}$  to be equal to the

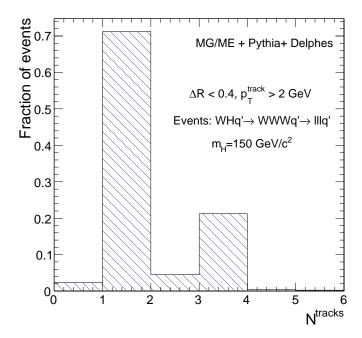

Figure 6: Distribution of the number of tracks  $N^{\text{tracks}}$  within a small jet cone for true  $\tau$ -jets, normalised to unity. Photoproduced WH events, where W bosons decay leptonically  $(e,\mu,\tau)$ , as in Fig. 5. Histogram entries correspond to true  $\tau$ -jets, matched with generator-level data.

 $\overrightarrow{p_T}$  vector sum of the invisible particles, written  $\overrightarrow{p_T}^{\text{miss}}$ .

$$\overrightarrow{p_T} = \begin{pmatrix} p_x \\ p_y \end{pmatrix} \text{ and } \begin{cases} p_x^{\text{miss}} = -p_x^{\text{obs}} \\ p_y^{\text{miss}} = -p_y^{\text{obs}} \end{cases}$$
(3)

The *true* missing transverse energy, i.e. at generator-level, is calculated as the opposite of the vector sum of the transverse momenta of all visible particles – or equivalently, to the vector sum of invisible particle transverse momenta. In a real experiment, calorimeters measure energy and not momentum. Any problem affecting the detector (dead channels, misalignment, noisy cells, cracks) worsens directly the measured missing transverse energy  $\overrightarrow{E_T}^{\text{miss}}$ . In *Delphes*, MET is based on the calorimetric cells only. Muons and neutrinos are therefore not taken into account for its evaluation:

$$\overrightarrow{E_T}^{\text{miss}} = -\sum_{i}^{\text{cells}} \overrightarrow{E_T}(i) \tag{4}$$

However, as muon candidates, tracks and calorimetric cells are available in the output file, the missing transverse energy can always be reprocessed a posteriori with more specialised algorithms.

## 4. Trigger emulation

Most of the usual trigger algorithms select events containing leptons, jets, and MET with an energy scale above some threshold. This is often expressed in terms of a cut on the transverse momentum of one or several objects of the measured event. Logical combinations of several conditions are also possible. For instance, a

trigger path could select events containing at least one jet and one electron such as  $p_T^{\rm jet} > 100~{\rm GeV}/c$  and  $p_T^e > 50~{\rm GeV}/c$ .

A trigger emulation is included in *Delphes*, using a fully parametrisable *trigger table* [x]. When enabled, this trigger is applied on analysis-object data. In a real experiment, the online selection is often divided into several steps (or *levels*). First-level triggers are fast and simple but based only on partial data as not all detector front-ends are readable within the decision latency. Higher level triggers are more complex, of finer-but-not-final quality and based on full detector data.

Real triggers are thus intrinsically based on reconstructed data with a worse resolution than final analysis data. On the contrary, same data are used in *Delphes* for trigger emulation and for final analyses.

# 5. Very forward detector simulation

Most of the recent experiments in beam colliders have additional instrumentation along the beamline. These extend the  $\eta$  coverage to higher values, for the detection of very forward final-state particles. In *Delphes*, Zero Degree Calorimeters, roman pots and forward taggers have been implemented (Fig. 7), similarly to the plans for CMS and ATLAS collaborations [5, 6].

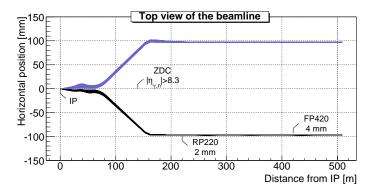

Figure 7: Default location of the very forward detectors, including ZDC, RP220 and FP420 in the LHC beamline. Incoming (beam 1, red) and outgoing (beam 2, black) beams on one side of the fifth interaction point (IP5, s=0 m on the plot). The Zero Degree Calorimeter is located in perfect alignment with the beamline axis at the interaction point, at 140 m, the beam paths are separated. The forward taggers are near-beam detectors located at 220 m and 420 m. Beamline simulation with Hector [7]. All very forward detectors are located symmetrically around the interaction point.

#### 5.1. Zero Degree Calorimeters

In direct sight of the interaction point, on both sides of the central detector, the Zero Degree Calorimeters (ZDCs) are located at zero angle, i.e. are aligned with the beamline axis at the interaction point. They are placed beyond the point where the paths of incoming and outgoing beams separate. These allow the measurement of stable neutral particles ( $\gamma$  and n) coming from the interaction point, with large pseudorapidities (e.g.  $|\eta_{n,\gamma}| > 8.3$  in ATLAS and CMS).

The trajectory of the neutrals observed in the ZDCs is a straight line, while charged particles are deflected away from their acceptance window by the powerful magnets located in front of them.

Table 5: Default parameters for the forward detectors: distance from the interaction point and detector acceptance. The LHC beamline is assumed around the fifth LHC interaction point (IP). For the ZDC, the acceptance depends only on the pseudorapidity  $\eta$  of the particle, which should be neutral and stable. It is expressed in terms of the particle energy (E). All detectors are located on both sides of the interaction point.

Detector	Distance	Acceptance	
ZDC	±140 m	$ \eta  > 8.3$	for $n$ and $\gamma$
RP220	±220 m	$E \in [6100; 6880] (GeV)$	at 2 mm
FP420	±420 m	$E \in [6880; 6980] (GeV)$	at 4 mm

The fact that additional charged particles may enter the ZDC acceptance is neglected in the current versions of *Delphes*.

The ZDCs have the ability to measure the time-of-flight of the particle. This corresponds to the delay t after which the particle is observed in the detector, with respect to the bunch crossing reference time at the interaction point  $(t_0)$ :

$$t = t_0 + \frac{1}{v} \times \left(\frac{s - z}{\cos \theta}\right) \approx \frac{1}{c} \times (s - z),$$
 (5)

where  $t_0$  is thus the true time coordinate of the vertex from which the particle originates, v the particle velocity, s is the ZDC distance to the interaction point, z is the longitudinal coordinate of the vertex,  $\theta$  is the particle emission angle. It is assumed that the neutral particle observed in the ZDC is highly relativistic and very forward. For the time-of-flight measurement, a Gaussian smearing can be applied according to the detector resolution (Tab. 6) [g].

The ZDCs are composed of an electromagnetic and a hadronic sections, for the measurement of photons and neutrons, respectively. The energy of the observed neutral is smeared according to Eq. 1 and the corresponding section resolutions (Tab. 6). The ZDC hits do not enter in the calorimeter cell list used for reconstruction of jets and missing transverse energy.

Table 6: Default values for the resolution of the zero degree calorimeters. Resolution on energy measurement is parametrised by the stochastic(S), noise(N) and constant(C) terms (Eq. 1) [g]. The time-of-flight is smeared according to a Gaussian function.

ZDC, electromag	hadronic part	
$S (\text{GeV}^{1/2})$		
N (GeV)	0	1.38
C	0.08	0.13
C		0.13
ZDC, timing reso		
$\sigma_t$ (s)	0	

The reconstructed ZDC hits correspond to neutral particles with a lifetime long enough to reach these detectors (default:  $c\tau \ge 140 \,\mathrm{m}$ ) and very large pseudorapidities (default:  $|\eta| > 8.3$ ). Photons are identified thanks to the electromagnetic section of the calorimeter, and if their energy overpasses a given threshold (def. 20 GeV). Similarly, neutrons are reconstructed according to the resolution of the hadronic section, if their energy exceeds a threshold (def. 50 GeV) [q].

#### 5.2. Forward taggers

Forward taggers (called here RP220, for "roman pots at 220 m" and FP420 for "forward proton taggers at 420 m", as at the LHC) are meant for the measurement of particles following very closely the beam path. Such devices, also used at HERA and Tevatron, are located very far away from the interaction point (further than 150 m in the LHC case).

To be able to reach these detectors, particles must have a charge identical to the beam particles, and a momentum very close to the nominal value of the beam. These taggers are near-beam detectors located a few millimetres from the true beam trajectory and this distance defines their acceptance (Tab. 5). For instance, roman pots at 220 m from the IP and 2 mm from the beam will detect all forward protons with an energy between 120 and 900 GeV [7]. In practice, in the LHC, only positively charged muons ( $\mu^+$ ) and protons can reach the forward taggers as other particles with a single positive charge coming from the interaction points will decay before their possible tagging. In *Delphes*, extra hits coming from the beam-gas events or secondary particles hitting the beampipe in front of the detectors are not taken into account.

While neutral particles propagate along a straight line to the ZDC, a dedicated simulation of the transport of charged particles is needed for RP220 and FP420. This fast simulation uses the *Hector* software [7], which includes the chromaticity effects and the geometrical aperture of the beamline elements of any arbitrary collider.

Forward taggers are able to measure the hit positions (x, y) and angles  $(\theta_x, \theta_y)$  in the transverse plane at the location of the detector (s meters away from the IP), as well as the time-of-flight (t). Out of these the particle energy (E) and the momentum transfer it underwent during the interaction  $(q^2)$  can be reconstructed at the analysis level (it is not implemented in the current versions of *Delphess*. The time-of-flight measurement can be smeared with a Gaussian distribution (default value  $\sigma_t = 0$  s) [y].

#### 6. Validation

*Delphes* performs a fast simulation of a collider experiment. Its performances in terms of computing time and data size are directly proportional to the number of simulated events and on the considered physics process. As an example,  $10,000 \ pp \rightarrow t\bar{t}X$  events are processed in 110 s on a regular laptop and use less than 250 MB of disk space. The quality and validity of the output are assessed by comparing the resolutions on the reconstructed data to the expectations of both CMS [5] and ATLAS [6] detectors.

Electrons and muons are by construction equal to the experiment designs, as the Gaussian smearing of their kinematics properties is defined according to the detector specifications. Similarly, the *b*-tagging efficiency (for real *b*-jets) and misidentification rates (for fake *b*-jets) are taken directly from the expected values of the experiment. Unlike these simple objects, jets and missing transverse energy should be carefully cross-checked.

 $<sup>^3</sup>$ It is worth noting that for both CMS and ATLAS experiments, the taggers located at 220 m are not able to measure the time-of-flight, contrary to FP420 detectors

#### 6.1. Jet resolution

The majority of interesting processes at the LHC contain jets in the final state. The jet resolution obtained using *Delphes* is therefore a crucial point for its validation, both for CMS- and ATLAS-like detectors. This validation is based on  $pp \rightarrow gg$  events produced with MadGraph/MadEvent and hadronised using *Pythia* [17, 18].

For a CMS-like detector, a similar procedure as the one explained in published results is applied here. The events were arranged in 14 bins of gluon transverse momentum  $\hat{p}_T$ . In each  $\hat{p}_T$  bin, every jet in *Delphes* is matched to the closest jet of generator-level particles, using the spatial separation between the two jet axes

$$\Delta R = \sqrt{(\eta^{\text{rec}} - \eta^{\text{MC}})^2 + (\phi^{\text{rec}} - \phi^{\text{MC}})^2} < 0.25.$$
 (6)

The jets made of generator-level particles, here referred as *MC jets*, are obtained by applying the algorithm to all particles considered as stable after hadronisation (i.e. including muons). Jets produced by *Delphes* and satisfying the matching criterion are called hereafter *reconstructed jets*. All jets are computed with the clustering algorithm (JetCLU) with a cone radius *R* of 0.7.

The ratio of the transverse energies of every reconstructed jet  $E_T^{\rm rec}$  to its corresponding MC jet  $E_T^{\rm MC}$  is calculated in each  $\hat{p}_T$  bin. The  $E_T^{\rm rec}/E_T^{\rm MC}$  histogram is fitted with a Gaussian distribution in the interval  $\pm 2$  RMS centred around the mean value. The resolution in each  $\hat{p}_T$  bin is obtained by the fit mean  $\langle x \rangle$  and variance  $\sigma^2(x)$ :

$$\frac{\sigma\left(\frac{E_T^{\text{rec}}}{E_T^{\text{MC}}}\right)_{\text{fit}}}{\left\langle\frac{E_T^{\text{ec}}}{E_T^{\text{MC}}}\right\rangle_{\text{fit}}} \left(\hat{p}_T(i)\right), \text{ for all } i.$$
 (7)

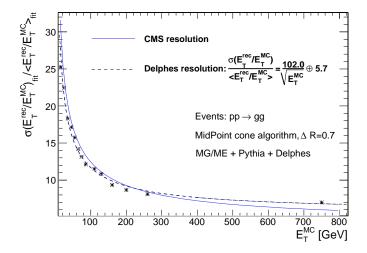

Figure 8: Resolution of the transverse energy of reconstructed jets  $E_{\rm T}^{\rm rec}$  as a function of the transverse energy of the closest jet of generator-level particles  $E_{\rm T}^{\rm MC}$ , in a CMS-like detector. The jets events are reconstructed with the JetCLU clustering algorithm with a cone radius of 0.7. The maximum separation between the reconstructed and MC-jets is  $\Delta R = 0.25$ . Dotted line is the fit result for comparison to the CMS resolution [5], in blue. The  $pp \to gg$  dijet events have been generated with MadGraph/MadEvent and hadronised with Pythia.

The resulting jet resolution as a function of  $E_T^{\rm MC}$  is shown in Fig. 8. This distribution is fitted with a function of the following

form:

$$\frac{a}{E_T^{\rm MC}} \oplus \frac{b}{\sqrt{E_T^{\rm MC}}} \oplus c, \tag{8}$$

where a, b and c are the fit parameters. It is then compared to the resolution published by the CMS collaboration [5]. The resolution curves from *Delphes* and CMS are in good agreement.

Similarly, the jet resolution is evaluated for an ATLAS-like detector. The  $pp \rightarrow gg$  events are here arranged in 8 adjacent bins in  $p_T$ . A  $k_T$  reconstruction algorithm with R=0.6 is chosen and the maximal matching distance between the MC-jets and the reconstructed jets is set to  $\Delta R=0.2$ . The relative energy resolution is evaluated in each bin by:

$$\frac{\sigma(E)}{E} = \sqrt{\left\langle \left(\frac{E^{\text{rec}} - E^{\text{MC}}}{E^{\text{rec}}}\right)^2 \right\rangle - \left\langle \frac{E^{\text{rec}} - E^{\text{MC}}}{E^{\text{rec}}} \right\rangle^2}.$$
 (9)

Figure 9 shows a good agreement between the resolution obtained with *Delphes*, the result of the fit with Equation 8 and the corresponding curve provided by the ATLAS collaboration [6].

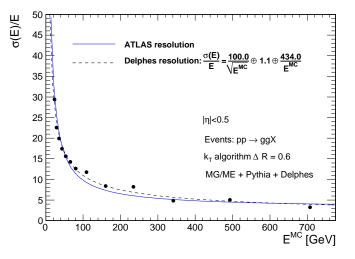

Figure 9: Relative energy resolution of reconstructed jets as a function of the energy of the closest jet of generator-level particles  $E^{\rm MC}$ , in an ATLAS-like detector. The jets are reconstructed with the  $k_T$  algorithm with a radius R=0.6. The maximal matching distance between MC- and reconstructed jets is  $\Delta R=0.2$ . Only central jets are considered ( $|\eta|<0.5$ ). Dotted line is the fit result for comparison to the ATLAS resolution [6], in blue. The  $pp \to gg$  di-jet events have been generated with MadGraph/MadEvent and hadronised with Pvthia.

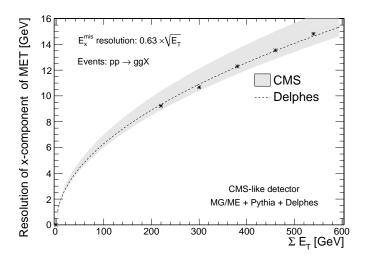

# 6.2. MET resolution

All major detectors at hadron colliders have been designed to be as much hermetic as possible in order to detect the presence of one or more neutrinos and/or new weakly interacting particles through apparent missing transverse energy. The resolution of the  $\overrightarrow{E_T}^{\text{miss}}$  variable, as obtained with *Delphes*, is then crucial.

The samples used to study the MET performance are identical to those used for the jet validation. It is worth noting that the contribution to  $E_T^{\rm miss}$  from muons is negligible in the studied sample. The input samples are divided in five bins of scalar  $E_T$  sums ( $\Sigma E_T$ ). This

sum, called *total visible transverse energy*, is defined as the scalar sum of transverse energy in all cells. The quality of the MET reconstruction is checked via the resolution on its horizontal component  $E_x^{\text{miss}}$ .

 $E_x^{\rm miss}$ . The  $E_x^{\rm miss}$  resolution is evaluated in the following way. The distribution of the difference between  $E_x^{\rm miss}$  in *Delphes* and at generator-level is fitted with a Gaussian function in each  $(\Sigma E_T)$  bin. The fit RMS gives the MET resolution in each bin. The resulting value is plotted in Fig. 10 as a function of the total visible transverse energy, for CMS- and ATLAS-like detectors.

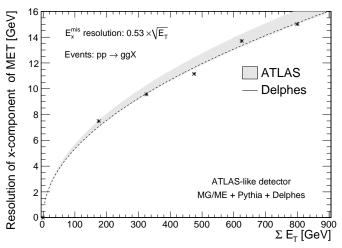

Figure 10:  $\sigma(E_x^{\text{mis}})$  as a function on the scalar sum of all cells  $(\Sigma E_T)$  for  $pp \to gg$  events, for a CMS-like detector (top) and an ATLAS-like detector (bottom), for dijet events produced with MadGraph/MadEvent and hadronised with *Pythia*.

The resolution  $\sigma_x$  of the horizontal component of MET is observed to behave like

$$\sigma_x = \alpha \sqrt{E_T} \quad (\text{GeV}^{1/2}), \tag{10}$$

where the  $\alpha$  parameter depends on the resolution of the calorimeters.

The MET resolution expected for the CMS detector for similar events is  $\sigma_x = (0.6 - 0.7) \sqrt{E_T} \text{ GeV}^{1/2}$  with no pile-up (i.e. extra simultaneous pp collision occurring at high-luminosity in the same

bunch crossing) [5], which compares very well with the  $\alpha = 0.63$  obtained with *Delphes*. Similarly, for an ATLAS-like detector, a value of 0.53 is obtained by *Delphes* for the  $\alpha$  parameter, while the experiment expects it in the range [0.53; 0.57] [6].

## 6.3. $\tau$ -jet efficiency

Due to the complexity of their reconstruction algorithm,  $\tau$ -jets have also to be checked. Table 7 lists the reconstruction efficiencies in *Delphes* for the hadronic  $\tau$ -jets from  $H,Z \to \tau^+\tau^-$ . The mass of the Higgs boson is set successively to 140 and 300 GeV/ $c^2$ . The inclusive gauge boson productions ( $pp \to HX$  and  $pp \to ZX$ ) are performed with MadGraph/MadEvent and the  $\tau$  lepton decay and further hadronisation are handled by *Pythia/Tauola*. All reconstructed  $\tau$ -jets are 1–prong, and follow the definition described in section 3.3, which is very close to an algorithm of the CMS experiment [19]. At last, corresponding efficiencies published by the CMS and ATLAS experiments are quoted for comparison. The agreement is good enough at this level to validate the  $\tau$ -reconstruction.

Table 7: Reconstruction efficiencies of  $\tau$ -jets in  $\tau^+\tau^-$  decays from Z or H bosons, in *Delphes*, CMS and ATLAS experiments [19, 6]. Two scenarios for the mass of the Higgs boson are investigated. Events generated with MadGraph/MadEvent and hadronised with *Pythia*. The decays of  $\tau$  leptons is handled by the *Tauola* version embedded in *Pythia*.

	CMS	Delphes	ATLAS	Delphes
$Z  ightarrow  au^+ au^-$	38.2%	$32.4 \pm 1.8\%$	33%	$28.6 \pm 1.9\%$
$H(140) \rightarrow \tau^+ \tau^-$	36.3%	$39.9 \pm 1.6\%$		$32.8 \pm 1.8\%$
$H(300) \rightarrow \tau^+ \tau^-$	47.3%	$49.7 \pm 1.5\%$		$43.8 \pm 1.6\%$

## 7. Visualisation

When performing an event analysis, a visualisation tool is useful to convey information about the detector layout and the event topology in a simple way. The *Fast and Realistic OpenGL Displayer* FROG [20] has been interfaced in *Delphes*, allowing an easy display of the defined detector configuration [z].

Two and three-dimensional representations of the detector configuration can be used for communication purposes, as they clearly illustrate the geometric coverage of the different detector subsystems. As an example, the generic detector geometry assumed in this paper is shown in Fig. 2 and 11. The extensions of the central tracking system, the central calorimeters and both forward calorimeters are visible. Note that only the geometrical coverage is depicted and that the calorimeter segmentation is not taken into account in the drawing of the detector. Moreover, both the radius and the length of each sub-detectors are just display parameters and are not relevant for the physics simulation.

Deeper understanding of interesting physics processes is possible by displaying the events themselves. The visibility of each set of objects  $(e^{\pm}, \mu^{\pm}, \tau^{\pm}, \text{jets}, \text{transverse missing energy})$  is enhanced

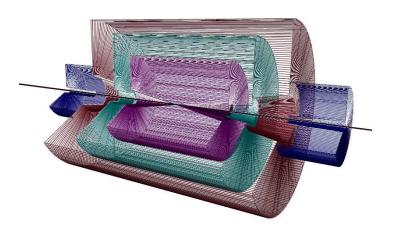

Figure 11: Layout of the generic detector geometry assumed in *Delphes*. Open 3D-view of the detector with solid volumes. Same colour codes as for Fig. 2 are applied. Additional forward detectors are not depicted.

by a colour coding. Moreover, kinematics information of each object is visible by a simple mouse action. As an illustration, an associated photoproduction of a W boson and a t quark is shown in Fig. 12. This corresponds to a  $pp(\gamma p \rightarrow Wt)pX$  process, where the Wt couple is induced by an incoming photon emitted by one of the colliding proton [21]. This leading proton survives after photon emission and is present in the final state. As the energy and virtuality of the emitted photon are low, the surviving proton does not leave the beam and escapes from the central detector without being detected. The experimental signature is a lack of hadronic activity in the forward hemisphere where the surviving proton escapes. The t quark decays into a W boson and a b quark. Both W bosons decay into leptons  $(W \to \mu \nu_{\mu} \text{ and } W \to e \nu_{e})$ . The balance between the missing transverse energy and the charged lepton pair is clear, as well as the presence of an empty forward region. It is interesting to notice that the reconstruction algorithms build a fake  $\tau$ -jet around the electron.

For comparison, Fig. 13 depicts an inclusive gluon pair production  $pp \to ggX$ . The event final state contains more jets, in particular along the beam axis, which is expected as the interacting protons are destroyed by the collision. Two muon candidates and large missing transverse energy are also visible.

## 8. Conclusion and perspectives

We have described here the major features of the *Delphes* framework, introduced for the fast simulation of a collider experiment. This framework is a tool meant for feasibility studies in phenomenology, gauging the observability of model predictions in collider experiments.

Delphes takes as an input the output of event-generators and yields analysis-object data in the form of TTree in a \*.root file. The simulation includes central and forward detectors to produce realistic observables using standard reconstruction algorithms. Moreover, the framework allows trigger emulation and 3D event visualisation.

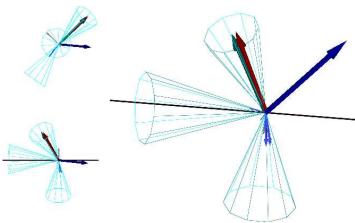

Figure 12: Example of  $pp(\gamma p \to Wt)pY$  event display in different orientations, with  $t \to Wb$ . One W boson decays into a  $\mu\nu_{\mu}$  pair and the second one into a  $e\nu_{e}$  pair. The surviving proton leaves a forward hemisphere with no hadronic activity. The isolated muon is shown as the dark blue vector. Around the electron, in red, is reconstructed a fake  $\tau$ -jet (green vector surrounded by a blue cone), while the reconstructed missing energy (in grey) is very small. One jet is visible in one forward region, along the beamline axis, opposite to the direction of the escaping proton.

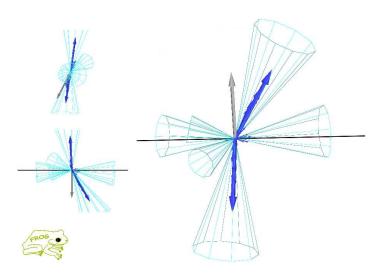

Figure 13: Example of inclusive gluon pair production  $pp \to ggX$ . Many jets are visible in the event, in particular along the beam axis. Two muons (in blue) are produced and the missing transverse energy is significant in this event (grey vector).

Delphes has been developed using the parameters of the CMS experiment but can be easily extended to ATLAS and other non-LHC experiments, as at Tevatron or at the ILC. Further developments include a more flexible design for the subdetector assembly, a better *b*-tag description and possibly the implementation of an event mixing module for pile-up event simulation. This framework has already been used for several analyses [21, 22, 23], in particular in photon-induced interactions at the LHC.

#### Acknowledgements

The authors would like to thank Jerôme de Favereau, Christophe Delaere, Muriel Vander Donckt and David d'Enterria for useful discussions and comments, and Loic Quertenmont for support in interfacing FROG. We are also really grateful to Alice Dechambre and Simon de Visscher for being beta testers of the complete package. Part of this work was supported by the Belgian Federal Office for Scientific, Technical and Cultural Affairs through the Interuniversity Attraction Pole P6/11.

#### Internal code references

- [a] The standard Monte Carlo event structures StdHEP [25] and HepMC [26] can be used as an input. Besides, *Delphes* can also provide detector response for events read in "Les Houches Event Format" (LHEF [27]) and \*.root files obtained from \*.hbook using the h2root utility from the ROOT framework [3]. See the following classes: HEPEVTConverter, HepMCConverter, LHEFConverter, STDHEPConverter and DelphesRootConverter.
- [b] The ROOT output files are created using the ExRootAnalysis utility [4]. Generator-level data are located under the GEN tree, the analysis data objects after reconstruction under the Analysis tree, and the results of the trigger emulation under the Trigger tree.
- [c] Set the FLAG\_LHCO variable to 1 or 0 in the detector card to switch on/off the creation of \*.lhco output file.
- [d] The list of particles considered as invisible is accessible in the PdgParticle class. This list currently contains the PIDs 12, 14, 16, 1000022, 1000023, 1000025, 1000035 and 1000045, in absolute values.
- [e] The detector card is the data/DetectorCard.dat file. This file is parsed by the SmearUtil class.

- [f] Detector and trigger cards for the ATLAS and CMS experiments are also provided in data/ directory.
- [g] The resolution terms in the detector card are named ELG\_Xyyy or HAD\_Xyyy, refering to electromagnetic and hadronic terms (resp.); X is replaced by S, N, C for the stochastic, noise and constant terms; and finally yyy is cen for central part, ec for end-caps, fwd for the forward calorimeters and zdc for the zerodegree calorimeters.
- [h] See the TrackPropagation class.
- [i] See the TRACK\_eff and TRACK\_ptmin terms in the detector card.
- The response of the detector is applied to the electromagnetic and the hadronic particles through the SmearElectron and SmearHadron methods in the SmearUtil class.
- [k] To implement different ratios for other particles, see the BlockClasses class.
- [1] As the detector is assumed to be cylindrical (e.g. symmetric in  $\phi$  and with respect to the  $\eta=0$  plane), the detector card stores the number of calorimetric cells with  $\phi=0$  and  $\eta>0$  (default: 40 cells). For a given  $\eta$ , the size of the  $\phi$  segmentation is also specified. See the TOWER\_number, TOWER\_eta\_edges and TOWER\_dphi variables in the detector card.
- [m] All these processed data are located under the Analysis tree.
- [n] See the SmearMuon method in the SmearUtil class.
- [0] See the IsolFlag and IsolPt values in the Electron or Muon collections in the Analysis tree, as well as the ISOL\_PT and ISOL\_Cone variables in the detector card.
- [p] Calorimetric isolation parameters in the detector card are ISOL\_Calo\_ET and ISOL\_Calo\_Grid in the detector card.
- [q] These thresholds are defined by the ZDC\_gamma\_E and ZDC\_n\_E variables in the detector card.
- [r] The choice is done by allocating the JET\_jetalgo input parameter in the detector card.
- [s] See the PTCUT\_jet variable in the detector card.
- [t] See the JET\_coneradius and JET\_seed variables in the detector card. The existing FastJet code has been modified to allow easy modification of the cell pattern in  $(\eta, \phi)$  space. In following versions of *Delphes*, a new dedicated plugin will be created on this purpose.
- [u] Set JET\_Eflow to 1 or 0 in the detector card in order to switch on or off the energy flow for jet reconstruction.
- [v] Corresponding to the BTAG\_b, BTAG\_mistag\_c and BTAG\_mistag\_l constants, for the efficiency of tagging of a b-jet, the efficiency of mistagging a c-jet as a b-jet, and the efficiency of mistagging a light jet (u,d,s,g) as a b-jet.
- [w] See the following parameters in the detector card: TAU\_energy\_scone for  $R^{\rm em}$ ; JET\_M\_seed for min  $E_T^{\rm cell}$ ; TAU\_energy\_frac for  $C_{\tau}$ ; TAU\_track\_scone for  $R^{\rm tracks}$ ; PTAU\_track\_pt for min  $p_T^{\rm tracks}$  and TAUJET\_pt for min  $p_T$ .
- [x] The trigger card is the data/TriggerCard.dat file. Default trigger files are also available for CMS-like and ATLAS-like detectors
- [y] The resolution is defined by the RP220\_T\_resolution and RP420\_T\_resolution parameters in the detector card.
- [z] To prepare the visualisation, the FLAG $\_$ FROG parameter should be equal to 1.

#### A. User manual

The available C++-code is compressed in a zipped tar file which contains everything needed to run the *Delphes* package, assuming a running ROOT installation. The package includes ExRootAnalysis [4], *Hector* [7], FastJet [8], and FROG [20], as well as the conversion codes to read standard StdHEP input files (mcfio and stdhep) [24] and HepMC [26]. In order to visualise the events with the FROG software, a few additional external libraries may be required, as explained in http://projects.hepforge.org/FROG/.

#### A.1. Getting started

In order to run *Delphes* on your system, first download its sources and compile them:

```
wget http://www.fynu.ucl.ac.be/users/s.ovyn/Delphes/files/Delphes_V_*.tar.gz
```

Replace the \* symbol by the proper version number. Always refer to the download page on the *Delphes* website http://www.fynu.ucl.ac.be/users/s.ovyn/Delphes/download.html. Current version of Delphes for this manual is V 1.8 (July 2009).

```
me@mylaptop:~$ tar -xvf Delphes_V_*.tar.gz
me@mylaptop:~$ cd Delphes_V_*.*
me@mylaptop:~$ ./genMakefile.tcl > Makefile
me@mylaptop:~$ make
```

Due to the large number of external utilities, the number of printed lines during the compilation can be high. The user should not pay attention to possible warning messages, which are due to the external packages used by *Delphes*. When compilation is completed, the following message is printed:

```
me@mylaptop:~$ Delphes has been compiled
me@mylaptop:~$ Ready to run
```

#### A.2. Running Delphes on your events

In this sub-appendix, we will explain how to use *Delphes* to perform a fast simulation of a general-purpose detector on your event files. The first step to use *Delphes* is to create the list of input event files (e.g. inputlist.list). It is important to notice that all the files comprised in the list file should have the same of extension (\*.hep, \*.lhe, \*.hepmc or \*.root). In the simplest way to run *Delphes*, you need this input file and you need to specify the name of the output file that will contain the generator-level data (GEN tree), the analysis data objects after reconstruction (Analysis tree), and the results of the trigger emulation (Trigger tree).

```
me@mylaptop:~$ ./Delphes inputlist.list OutputRootFileName.root
```

## A.2.1. Setting up the configuration

The program is driven by two datacards (default cards are data/DetectorCard.dat and data/TriggerCard.dat) which allow the user to choose among a large spectrum of running conditions. Please note that if the user does not provide these datacards, the running will be done using the default parameters defined in the constructor of the class RESOLution (see next). If you choose a different detector or running configuration, you will need to edit the datacards accordingly. Detector and trigger cards are provided in the data/ subdirectory for the CMS and ATLAS experiments.

- 1. **The detector card** It contains all pieces of information needed to run *Delphes*:
  - detector parameters, including calorimeter and tracking coverage and resolutions, transverse energy thresholds for object reconstruction and jet algorithm parameters.
  - six flags (FLAG\_bfield, FLAG\_vfd, FLAG\_RP, FLAG\_trigger, FLAG\_FROG and FLAG\_LHCO), should be set in order to configure the magnetic field propagation, the very forward detectors simulation, the use of very forward taggers, the trigger selection, the preparation for FROG display and the creation of an output file in \*.LHCO text format (respectively).

If no datacard is provided by the user, the default smearing and running parameters are used (corresponding to tables 1, 2). Definition of the sub-detector extensions:

```
CEN_max_tracker 2.5 // Maximum tracker coverage
CEN_max_calo_cen 1.7 // central calorimeter coverage

                 5.000
```

TOWER\_eta\_edges is the list of the edges in  $\eta$  of all cells, in the  $\eta > 0$  hemisphere (the detector is supposed to be symmetric with respect to the  $\eta = 0$  plane, as well as around the z-axis). Starts with the lower edge of the most central tower (default:  $\eta = 0$ ) and ends

with the higher edge of the most forward tower. TOWER\_dphi lists the tower size in  $\phi$  (in degree), assuming that all cells are similar in  $\phi$  for a given  $\eta$ .

Thresholds applied for storing the reconstructed objects in the final collections:

```
# Thresholds for reconstructed objects, in GeV/c
PTCUT_elec
                10.0
                 10.0

```

## Others parameters:

In general, energies, momenta and masses are expressed in GeV, GeV/c,  $\text{GeV}/c^2$  respectively, and magnetic fields in T. Geometrical extension are often referred in terms of pseudorapidity  $\eta$ , as the detectors are supposed to be symmetric in  $\phi$ . From version 1.8 onwards, the number of events to run is also be included in the detector card (NEvents). For version 1.7 and earlier, the parameters related to the calorimeter endcaps (CEN\_max\_calo\_ec, ELG\_Sec, ELG\_Nec, ELG\_Cec, HAD\_Sec, HAD\_Nec and HAD\_Cec) did not exist in the detector cards; in addition, some other variables had different names (HAD\_Scen was HAD\_Sfcal, HAD\_Ncen was HAD\_Nfcal, HAD\_Cen was HAD\_Sfwd was HAD\_Sfwd was HAD\_Nfwd was HAD\_Nhf, HAD\_Cfwd was HAD\_Chf). However, these cards are still completely compatible with new versions of *Delphes*. In such a case, the calorimeter endcaps are simply assumed to be located at the edge of the central calorimeter volumes, with the same resolution values.

# 2. The trigger card

This card contains the definitions of all trigger-bits. Cuts can be applied on the transverse momentum  $p_T$  of electrons, muons, jets,  $\tau$ -jets, photons and the missing transverse energy. The following codes should be used so that *Delphes* can correctly translate the input list of trigger-bits into selection algorithms:

```
Corresponding object
Trigger code
ELEC_PT
              electron
IElec_PT
              isolated electron
MUON_PT
              muon
IMuon_PT
              isolated muon
JET_PT
              jet
TAU_PT
              \tau-iet
              missing transverse energy
ETMIS_PT
GAMMA_PT
              photon
Bjet_PT
              b-jet
```

Each line in the trigger datacard is allocated to exactly one trigger-bit and starts with the name of the corresponding trigger. Logical combination of several conditions is also possible. If the trigger-bit requires the presence of multiple identical objects, the order of their  $p_T$  thresholds is very important: they must be defined in *decreasing* order. The transverse momentum  $p_T$  is expressed in GeV/c. Finally, the different requirements on the objects must be separated by a && flag. The default trigger card can be found in the data repository of Delphes (data/TriggerCard.dat), as well as for both CMS and ATLAS experiments at the LHC. An example of trigger table consistent with the previous rules is given here:

```
SingleJet >> JET_PT: '200'

DoubleElec >> ELEC_PT: '20' && ELEC_PT: '10'

SingleElec and Single Muon >> ELEC_PT: '20' && MUON_PT: '15'
```

#### A.2.2. Running the code

First, create the detector and trigger cards (data/DetectorCard.dat and data/TriggerCard.dat).

Then, create a text file containing the list of input files that will be used by *Delphes* (with extension \*.lhe, \*.hepmc, \*.root or \*.hep). To run the code, type the following command (in one line)

As a reminder, typing the ./Delphes command simply displays the correct usage:

```
me@mylaptop:~$ ./Delphes
Usage: ./Delphes input_file output_file [detector_card] [trigger_card]
input_list - list of files in Ntpl, StdHep, HepMC or LHEF format,
output_file - output file.
detector_card - Card containing resolution variables for detector simulation (optional)
trigger_card - Card containing the trigger algorithms (optional)
```

#### A.3. Getting the Delphes information

## A.3.1. Contents of the Delphes ROOT trees

The *Delphes* output file (\*.root) is subdivided into three *trees*, corresponding to generator-level data, analysis-object data and trigger output. These *trees* are structures that organise the output data into *branches* containing data (or *leaves*) related with each others, like the kinematics properties  $(E, p_x, \eta, ...)$  of a given particle.

Here is the exhaustive list of *branches* availables in these *trees*, together with their corresponding physical objet and ExRootAnalysis C++ class name:

## **GEN** Tree

Particle	GenParticle		
<b>Trigger</b> Tree TrigResult	Acceptance of different trigger-bits	TRootTrigger	
Analysis Tree			
Tracks	Collection of tracks	TRootTracks	
CaloTower	Calorimetric cells	TRootCalo	

Electron Collection of electrons TRootElectron Photon Collection of photons TRootPhoton Muon Collection of muons TRootMuon Collection of jets Jet TRootJet Collection of jets tagged as  $\tau$ -jets TauJet TRootTauJet**ETmis** Transverse missing energy information TRootETmis **ZDChits** Hits in the Zero Degree Calorimeters TRootZdcHits RP220hits Hits in the first proton taggers TRootRomanPotHits FP420hits Hits in the next proton taggers TRootRomanPotHits

The third column shows the names of the corresponding classes to be written in a ROOT tree. The bin number in the unique leaf in the trigger tree (namely, TrigResult.Accepted) corresponds to the trigger number in the provided list. In addition, the result of the global trigger decision upon each event (i.e. the logical OR of all trigger conditions) is stored in the first bin (number 0) of this leaf. In Analysis tree, all classes except TRootTracks, TRootCalo, TRootTrigger, TRootETmis and TRootRomanPotHits inherit from the class TRootParticle which includes the following data members (stored as *leaves* in *branches* of the *trees*):

#### Most common leaves

```
float E; // particle energy in GeV float Px; // particle momentum vector (x component) in GeV/c float Py; // particle momentum vector (y component) in GeV/c float Pz; // particle momentum vector (z component) in GeV/c float PT; // particle transverse momentum in GeV/c float Eta; // particle pseudorapidity float Phi; // particle azimuthal angle in rad
```

In addition to their kinematics, some additional properties are available for specific objects:

#### Leaves in the Particle branch (GEN tree)

# Additional leaves in Electron and Muon branches (Analysis tree)

#### Additional leaf in the Jet branch (Analysis tree)

```
bool Btag // stores the result of the b-tagging
int NTracks // number of tracks associated to the jet
float EHoverEE // hadronic energy over electromagnetic energy
```

## Leaves in the Tracks branch (Analysis tree)

```
float Eta // pseudorapidity at the beginning of the track float Phi // azimuthal angle at the beginning of the track float EtaOuter // pseudorapidity at the end of the track float PhiOuter // azimuthal angle at the end of the track float PT // track transverse momentum in GeV/c float E // track energy in GeV float Px // track momentum vector (x component) in GeV/c float Pz // track momentum vector (y component) in GeV/c float Charge // track charge in units of e
```

#### Leaves in the CaloTower branch (Analysis tree)

```
float Eta
                 // pseudorapidity of the cell
   float Phi
                  // azimuthal angle of the cell in rad
                  // cell energy in GeV
   float E
                  // electromagnetic component of the cell energy in GeV
   float E_em
                 // hadronic component of the cell energy in GeV
   float E_had
   float ET
                  // cell transverse energy in GeV
Leaves in the ETmis branch (Analysis tree)
```

```
// azimuthal angle of the transverse missing energy in rad
float Phi
              // transverse missing energy in GeV
float ET
float Px
              // x component of the transverse missing energy in GeV
float Py
               // y component of the transverse missing energy in GeV
```

The hits in very forward detector (ZDC, RP220, FP420) have some common data. In particular, the side variable tells in which detector (left:-1 or right:+1 of the interaction point) the hit has been seen. Moreover, some generator level data is provided for information, as the correspondance with the contents of the GEN tree is not possible. These generator-level data correspond to the particle kinematics (energy, momentum, angle) and identification (pid).

## Common leaves for ZDC, RP220, FP420

```
// time of flight in s
   float E
                   // measured/smeared energy in GeV
   int side
                   // -1 \text{ or } +1
Generator level data
                   // particle ID
   int pid;
   float genPx;
                   // particle momentum vector (x component) in GeV/c
   float genPy;
                   // particle momentum vector (y component) in GeV/c
                   // particle momentum vector (z component) in GeV/c
   float genPz;
   float genPT;
                   // particle transverse momentum in GeV/c
                   // particle pseudorapidity
   float genEta;
   float genPhi;
                   // particle azimuthal angle in rad
Additional leaves in the ZDChits branch (Analysis tree)
   int hadronic_hit // O(is not hadronic) or 1(is hadronic)
Additional leaves in the RP220hits and FP420hits branches (Analysis tree)
  flaot S
               // detector position from IP in m
   float X
               // hit horizontal position in m

   float TY
               // reconstructed momentum transfer in GeV^2
   float q2
```

The hit position is computed from the center of the beam position, not from the edge of the detector.

#### A.4. Deeper description of jet algorithms

In this section, we briefly describe the differences between the six jet algorithms interfaced in *Delphes*, via the FastJet utiliy [8]. Jet algorithms differ in their sensitivity to soft particles or collinear splittings, and in their computing speed performances. The first three belong to the cone algorithm class while the last three are using a sequential recombination scheme. For all of them, the calorimetric cells are used as inputs for the jet clustering.

## Cone algorithms

- 1. CDF Jet Clusters [9]: Basic cone reconstruction algorithm used by the CDF experiment in Run II). All cells lying in a circular cone around the jet axis with a transverse energy  $E_T$  higher than a given threshold are used to seed the jet candidates. This algorithm is fast but sensitive to both soft particles and collinear splittings.
- 2. CDF MidPoint [10]: Cone reconstruction algorithm developed for the CDF Run II to reduce infrared and collinear sensitivities compared to purely seed-based cone by adding 'midpoints' (energy barycentres) in the list of cone seeds.
- 3. Seedless Infrared Safe Cone [11]: The SISCone algorithm is simultaneously insensitive to additional soft particles and collinear splittings, and fast enough to be used in experimental analysis.

#### Recombination algorithms

The three sequential recombination jet algorithms are safe with respect to soft radiations (*infrared*) and collinear splittings. They rely on recombination schemes where calorimeter cell pairs are successively merged. The definitions of the jet algorithms are similar except for the definition of the *distances* d used during the merging procedure. Two such variables are defined: the distance  $d_{ij}$  between each pair of cells (i, j), and a variable  $d_{iB}$  (*beam distance*) depending on the transverse momentum of the cell i. The jet reconstruction algorithm browses the calorimetric cell list. It starts by finding the minimum value  $d_{\min}$  of all the distances  $d_{ij}$  and  $d_{iB}$ . If  $d_{\min}$  is a  $d_{ij}$ , the cells i and j are merged into a single cell with a four-momentum  $p^{\mu} = p^{\mu}(i) + p^{\mu}(j)$  (*E-scheme recombination*). If  $d_{\min}$  is a  $d_{iB}$ , the cell is declared as a final jet and is removed from the input list. This procedure is repeated until no cells are left in the input list. Further information on these jet algorithms is given here below, using  $k_{ti}$ ,  $y_i$  and  $\phi_i$  as the transverse momentum, rapidity and azimuth of calorimetric cell i and  $\Delta R_{ij} = \sqrt{(y_i - y_j)^2 + (\phi_i - \phi_j)^2}$  as the jet-radius parameter:

- 4. Longitudinally invariant  $k_t$  jet [12], with  $d_{ij} = \min(k_{ti}^2, k_{tj}^2) \times \frac{\Delta R_{ij}^2}{R^2}$  and  $d_{iB} = k_{ti}^2$ ,
- 5. Cambridge/Aachen jet [13], with  $d_{ij} = \frac{\Delta R_{ij}^2}{R^2}$  and  $d_{iB} = 1$ ,
- 6. Anti  $k_t$  jet [14], where hard jets are exactly circular in the  $(y, \phi)$  plane:  $d_{ij} = \min(1/k_{ti}^2, 1/k_{tj}^2) \times \frac{\Delta R_{ij}^2}{R^2}$  and  $d_{iB} = \frac{1}{k_{ti}^2}$ .

#### A.5. Running an analysis on your Delphes events

To analyse the ROOT ntuple produced by *Delphes*, the simplest way is to use the Analysis\_Ex.cpp code which is coming in the Examples repository of *Delphes*. Note that all of this is optional and done to facilitate the analyses, as the output from *Delphes* is viewable with the standard ROOT TBrowser and can be analysed using the MakeClass facility. As an example, here is a simple overview of a myoutput.root file created by *Delphes*:

```
me@mylaptop:~$ root -1 myoutput.root
Attaching file myoutput.root as _file0...
root [1] .ls
TFile**
                myoutput.root
TFile*
               myoutput.root
  KEY: TTree
                       Analysis tree
  KEY: TTree
                Analysis;1
                                Analysis tree
  KEY: TTree
                                Analysis tree
                Trigger; 1
root [2] TBrowser t;
root [3] Analysis->GetEntries()
(const Long64_t)200
root [4] GEN->GetListOfBranches()->ls()
OBJ: TBranchElement Event
                                 Event_ : 0 at: 0x9108f30
OBJ: TBranch
                     Event_size Event_size/I : 0 at: 0x910cfd0
OBJ: TBranchElement Particle
                                 Particle_: 0 at: 0x910c6b0
OBJ: TBranch Particle_size Particle_size/I: 0 at: 0x9111c58
root [5] Trigger->GetListOfLeaves()->ls()
OBJ: TLeafElement TrigResult_
                                       TrigResult_ : 0 at: 0x90f90a0
OBJ: TLeafElement TrigResult.Accepted Accepted[TrigResult_]: 0 at: 0x90f9000
OBJ: TLeafI
                 TrigResult_size
                                       TrigResult_size : 0 at: 0x90fb860
```

The .ls command lists the current keys available and in particular the three *tree* names. TBrowser t launches a browser and the GetEntries() method outputs the number of data in the corresponding *tree*. The list of *branches* or *leaves* can be displayed with the GetListOfBranches() and GetListOfLeaves() methods, pointing to the ls() one. In particular, it is possible to shown only parts of the output, using wildcard characters (\*):

```
root [6] Analysis->GetListOfLeaves()->ls("*.E")
OBJ: TLeafElement
                        Jet.E
                                        E[Jet_] : 0 at: 0xa08bc68
                                        E[TauJet_] : 0 at: 0xa148910
OBJ: TLeafElement
                        TauJet.E
                                        E[Electron_] : 0 at: 0xa1d8a50
OBJ: TLeafElement
                        Electron.E
                                        E[Muon_] : 0 at: 0xa28ac80
OBJ: TLeafElement
                        Muon.E
                                        E[Photon_] : 0 at: 0xa33cd88
OBJ: TLeafElement
                        Photon.E
OBJ: TLeafElement
                        Tracks.E
                                        E[Tracks_] : 0 at: 0xa3cced0
```

```
OBJ: TLeafElement CaloTower.E E[CaloTower]: 0 at: 0xa4ba188
OBJ: TLeafElement ZDChits.E E[ZDChits]: 0 at: 0xa54a3c8
OBJ: TLeafElement RP22Ohits.E E[RP22Ohits]: 0 at: 0xa61e648
OBJ: TLeafElement FP42Ohits.E E[FP42Ohits]: 0 at: 0xa6d0920
```

To draw a particular leaf, either double-click on the corresponding name in the TBrowser or use the Draw method of the corresponding *tree*.

```
root [7] Trigger->Draw("TrigResult.Accepted");
```

Mathematical operations on several *leaves* are possible within a given *tree*, following the C++ syntax:

```
root [8] Analysis->Draw("Muon.Px * Muon.Px");
root [9] Analysis->Draw("sqrt(pow(Muon.E,2) - pow(Muon.Pz,2) + pow(Muon.PT,2))");
```

Finally, to prepare an deeper analysis, the MakeClass method is useful. It creates two files (\*.h and \*.C) with automatically generated code that allows the access to all branches and leaves of the corresponding tree:

For more information, refer to ROOT documentation. Moreover, an example of code (based on the output of MakeClass) is provided in the Examples/directory.

To run the Examples/Analysis Ex. cpp code, the two following arguments are required: a text file containing the input *Delphes* root files to run, and the name of the output root file.

```
me@mylaptop:~$ ./Analysis_Ex input_file.list output_file.root
```

One can easily edit, modify and compile (make) changes in this file.

#### A.5.1. Adding the trigger information

The Examples/Trigger\_Only.cpp code permits to run the trigger selection separately from the general detector simulation on output *Delphes* root files. A *Delphes* root file is mandatory as an input argument for the Trigger\_Only routine. The new *tree* containing the trigger result data will be appended to this file. The trigger datacard is also necessary. To run the code:

```
me@mylaptop:~$ ./Trigger_Only input_file.root data/TriggerCard.dat
```

#### A.6. Running the FROG event display

- If the FLAG\_FROG was switched on in the smearing card, two files have been created during the running of *Delphes*: DelphesToFROG.vis and DelphesToFROG.geom . They contain all the needed pieces of information to run FROG.
- To display the events and the geometry, you first need to compile FROG. Go to the Utilities/FROG and type make. This compilation is done once for all, with this geometry (i.e. as long as the \*vis and \*geom files do not change).
- Go back into the main directory and type

```
me@mylaptop: $ ./Utilities/FROG/FROG
```

## A.7. LHCO file format

The \*LHCO file format is a text-ASCII data format briefly discussed here. An exhaustive description is provided on http://v1.jthaler.net/olympicswiki. This section is based on this webpage. Only final high-level objects are available in the LHCO format, and their properties are arranged in columns. Each row corresponds to an object in the event and all events are written after each other. Comment-lines starts with a hash # symbol.

#	typ	eta	phi	pt	jmas	ntrk	btag	had/em	dum1	dum2
0		57	0							
1	0	1.392	-2.269	19.981	0.000	0.000	0.000	4.605	0.000	0.000
2	3	1.052	2.599	29.796	3.698	-1.000	0.000	0.320	0.000	0.000
3	4	1.542	-2.070	84.308	41.761	7.000	0.000	1.000	0.000	0.000
4	4	1.039	0.856	58.992	34.941	1.000	0.000	1.118	0.000	0.000
5	4	1.052	2.599	29.796	3.698	0.000	0.000	0.320	0.000	0.000
6	4	0.431	-2.190	22.631	3.861	0.000	0.000	1.000	0.000	0.000
7	6	0.000	0.845	62.574	0.000	0.000	0.000	0.000	0.000	0.000

Each row in an event starts with a unique number (i.e. in first column). Row 0 contains the event number (here: 57) and some trigger information (here: 0. This very particular trigger encoding is not implemented in *Delphes*.). Subsequent rows list the reconstructed high-level objects. Each row is organised in columns, which details the object kinematics as well as more specific information, such as isolation criteria or *b*-tagging.

*1st column (#).* The first column is the line number in the event. Each event starts with a 0 and contains as many lines as needed to list all high-level objects.

2nd column (typ). The second column gives the object identification code, or type. The different object types are:

- 0 for a photon  $(\gamma)$
- 1 for an electron  $(e^{\pm})$
- 2 for a muon  $(\mu^{\pm})$
- 3 for a hadronically-decaying tau ( $\tau$ -jet)
- 4 for a jet
- 6 for a missing transverse energy ( $E_T^{\text{miss}}$ )

Object type 5 is not defined. An event always ends with the row corresponding to the missing transverse energy (type 6).

 $3rd\ (eta)\ and\ 4th\ (phi)\ columns$ . The third and forth columns gives the object pseudorapidity  $\eta$  and azimuth  $\phi$ . This latter quantity is expressed in radians, ranging from  $-\pi$  to  $\pi$ .

5th (pt) and 6th (jmass) columns. The fifth column provides the object transverse momentum ( $p_T$  in GeV/c) or energy ( $E_T$  in GeV), while the invariant mass (M in GeV/ $c^2$ ) is in the sixth column.

7th column (ntrk). The seventh column reports the total number of tracks associated to the objects. This is 0 for photons,  $\pm$  1 for charged leptons including taus (where the sign reports the lepton measured charge) and a positive number ( $\geq$  0) for jets.

8th column (btag). The eighth column tells whether a jet is tagged as a b-jet (1) or not (0). This is always 0 for electrons, photons and missing transverse energy. For muons, the closest jet in searched for, in terms of  $\Delta R$ . The integer-part of the quoted number is the row-number (column 1) of this jet.

9th column (had/em). For jets, electrons and photons, the ninth column is the ration between hadronic and electromagnetic energies in the calorimetric cells associated to the object. This is always 0 for missing transverse energy. For muons, this number (aaa.bb) reports two values related to the muon isolation (section 3.1). The integer part (aaa) is transverse momentum sum  $P_T$  (in GeV/c) and the fractional part (bb) is the energy ratio  $\rho_\mu$ .

10th and 11th columns (dum1 and dum2). The last two columns are currently not used.

Warning. Inherently to the data format itself, the \*LHCO output contains only a fraction of the available data. Moreover, dealing with text file may have various drawbacks, such as the output file size and the time needed for its creation. Whenever possible, working on the \*root output file should be preferred.
